

On the Physical, Physiological, and Information-Theoretic Impossibility of Alex Wu Having Read *The Co-Scientist* *Thesis* in Thirteen Minutes

*A Multidisciplinary Investigation into a Claim That Cannot, Under Any Reading of
the Laws of Optics, Neurophysiology, Thermodynamics, or Common Decency, Be
True*

A research thesis submitted in fulfilment of no requirement whatsoever,
and entirely on the initiative of the present author,
in defence of the integrity of the reading record.

Volume I of I · 398 claims considered · one claimant indicted

R. M. H.
Principal Investigator, Reading Feasibility Group

June 2026

“I read the whole thing. It was fine. Took me about thirteen minutes.”

— Alex Wu, allegedly, on a Tuesday

“Extraordinary claims require extraordinary evidence.”

— Carl Sagan, who never met Alex

This document is offered in a spirit of rigorous friendship. No Alex was harmed in its preparation, though several were gently corrected.

Abstract

On the eighteenth of June, 2026, the subject of this investigation — Mr. Alex Wu — asserted that he had read *The Co-Scientist Thesis*, a document of 3,365 pages and 2,500,037 words, in its entirety, in thirteen (13) minutes. This thesis examines that assertion across six independent domains of evidence: the arithmetic of reading rate; the ocular mechanics of saccadic eye movement; the optics of foveal acuity; the information theory of the comprehension channel; the established empirical literature on speed reading; and the cognitive psychology of memory and retention.

We find that the claim requires a sustained reading rate of **192,311 words per minute** — approximately 808 times the rate of a competent adult reader, and roughly 192 times the most generous figure ever printed on the packaging of a speed-reading course. We show that this rate would allot each word 0.312 milliseconds of the reader's attention; would demand 801 words be absorbed per available eye fixation, where the human maximum is approximately one; and would require the claimant to turn a fresh, fully-comprehended page every 231.8 milliseconds — faster than he could voluntarily blink.

Every line of evidence converges, without exception and without remaining ambiguity, on a single conclusion. We state it plainly in Chapter 24, but the reader of even this abstract may already anticipate it. Honest reading of the document at a normal pace would require approximately **175.1 hours** of continuous attention — about 29.2 calendar days at a humane six hours per day. Thirteen minutes buys 3,094 words: roughly 4.2 pages, or 0.1238% of the work. We conclude that Mr. Wu did not read it.

Keywords: reading rate; saccadic suppression; foveal acuity; Ebbinghaus decay; Shannon channel capacity; speed-reading; parafoveal preview; the limits of friendship.

Acknowledgements

The author thanks Alex Wu, without whose confidence this work would have no subject. I thank Hermann Ebbinghaus (1850–1909), who measured forgetting so that we might quantify Alex's. I thank Keith Rayner (1943–2015), whose four decades of eye-tracking research establish, line by line, exactly how a human eye moves across a page — and therefore how Alex's did not. I thank the manufacturers of the speed-reading courses whose advertising copy, taken at its own most heroic word, still falls short of the claim by a factor of 192.

I thank the document itself, all 2,500,037 words of it, for being long enough to render the matter unambiguous. Had it been a pamphlet, we would have nothing to discuss. It is not a pamphlet.

Finally I thank the reader, who — should they finish this thesis — will have demonstrably spent more time reading *about* the document than Alex claims to have spent reading the document. This is the point. Welcome.

Part I

The Claim and the Corpus

*In which a claim is entered into the record, the accused document is measured
to the word, and the arithmetic alone is found to be sufficient grounds for
alarm.*

CHAPTER 1

Introduction: A Claim Enters the Record

Every field has its foundational anomaly — the observation so far outside the expected that it forces a discipline into being. Astronomy had the anomalous perihelion of Mercury. Thermodynamics had the heat death. The present field, which we propose to call *forensic bibliometrics*, has Alex Wu and his thirteen minutes.

The facts are not in dispute, because Mr. Wu volunteered them freely and, by all accounts, cheerfully. Presented with *The Co-Scientist Thesis* — a strategic and technical master specification running to 3,365 pages and 2,500,037 words — he reported, after an interval of approximately thirteen minutes, that he had read ‘the entire thing,’ and that it was ‘fine.’ He offered no caveat. He did not say he had skimmed it, sampled it, or formed an impression of it. He said he had read it.

This thesis takes that claim seriously — far more seriously, we suspect, than it was issued. We take it seriously because it is the only honest response to a friend who has told you something that cannot be true: not to wave it away, but to determine, with as much rigour as the matter can bear, *exactly* how untrue it is, and to present the finding in a form he cannot read in thirteen minutes either.

1.1 The structure of the argument

We do not rest the case on a single calculation, though a single calculation would suffice. Instead we assemble six independent arguments, each drawn from a different discipline, each sufficient on its own to defeat the claim, and each arriving — by an entirely separate road — at the same destination. The arguments are: the arithmetic (Chapter 4); the physiological (Part II); the information-theoretic (Part III); the empirical literature on speed reading (Part IV); the merely physical question of whether the pages could be turned (Part V); and the cognitive question of whether anything could have been retained (Part VI). We then consider, and dismiss, every defence the claimant might raise (Part VII), and propose an experiment that would settle the matter in a afternoon (Part VIII).

1.2 A note on tone

The reader will detect, beneath the apparatus of figures and citations, a certain warmth. This is intentional. The purpose of the document is not to humiliate Mr. Wu but to honour him: no one builds a 190-page instrument to refute a person they do not like. We refute him at length precisely because the friendship can bear it. He claimed the impossible; we have answered with the disproportionate. This is how it should be.

1.3 On proportion, and why this volume is long

A reader encountering a 190-page rebuttal to a single offhand sentence may reasonably ask whether the response is proportionate. It is not, and the disproportion is deliberate and load-bearing. The claim’s defining property is a mismatch of scale: a vast object (2.5 million words) was said to have been processed in a tiny interval (thirteen minutes). The only honest way to *feel* that mismatch, rather than merely concede it, is to restore the missing scale somewhere — and we have chosen to restore it here, in the length of the reply. The thesis is long because the document is long; it is thorough because the claim was casual; and it takes many minutes to read because that is precisely the resource whose sufficiency is in dispute. Form, here, is argument.

There is also a methodological reason. A short refutation invites a short rebuttal; a single calculation can be waved away as a single calculation. By assembling six independent disproofs, each from a mature science, we make the claim's defence a war on six fronts at once. To rescue the thirteen minutes, Mr. Wu would need to overturn not one inconvenient number but the eye-movement literature, the psychophysics of the retina, Shannon's channel theorem, the empirical record of speed reading, the motor limits of the hand, and a century of memory research — simultaneously, and in his favour. We consider this unlikely.

1.4 Scope and limits

We restrict ourselves to the claim as stated: a complete reading, with the ordinary implication of comprehension, in thirteen minutes. We do not investigate *why* Mr. Wu made the claim, that being a question of psychology rather than physics, and one on which we lack data and decline to speculate. We do not assess the quality of the document he claimed to have read; its merits are irrelevant to whether it could be read in the time. And we do not impugn Mr. Wu's character. Our quarrel is with a sentence, not a man — a sentence that happens to be false, and happens to belong to a friend.

The Central Claim, Stated Formally

Claim (Wu). There exists a reading event of duration $t = 13$ min during which the subject consumed, with comprehension, the entirety of a corpus of $W = 2,500,037$ words.

This thesis. The claim is false. We prove it six times.

CHAPTER 2

The Subject and the Assertion

2.1 The subject

Mr. Alex Wu is, by every account available to this investigation, a capable and intelligent individual. We stipulate this at the outset because it matters to the argument. Nothing that follows depends on Mr. Wu being a poor reader. On the contrary: we will grant him, at every turn, the most flattering assumptions the literature permits. We will assume he reads faster than average. We will assume he never tires, never blinks wastefully, never re-reads a sentence, never pauses to think. We will, in places, assume he reads faster than any human being has ever been documented to read. The claim fails anyway, and by enormous margins. That is the point of granting the assumptions: a claim that fails even under maximally charitable conditions is not a close call.

2.2 The assertion and its timestamp

The document under examination carries, in its own metadata, a creation timestamp of 18 June 2026, 19:26 UTC. The assertion was made shortly thereafter. The thirteen-minute figure is Mr. Wu's own; we have not rounded it, inflated it, or otherwise manipulated it to strengthen the case. Had he claimed thirteen *hours*, this thesis would still find against him, though it would be a shorter and sadder document. He claimed thirteen minutes. We proceed on that figure exactly.

2.3 What ‘reading’ means

A great deal turns on the word *read*, and Mr. Wu’s defenders — should he retain any after the publication of this volume — will be tempted to litigate it. We therefore fix the definition now. To *read* a text, in the sense relevant to the claim, is to move the eyes across its words in sequence such that the words are lexically accessed and their meaning is, at least transiently, represented in the mind. This is the ordinary meaning. It excludes holding the document, scrolling past it, photographing it, or forming a vague sense of its heft. We will consider those weaker activities in Part VII and show that even they cannot be completed in the time. But the claim was *read*, and *read* is what we will hold him to.

Lemma 2.1 (Charitable Framing)
Throughout this thesis the claimant is granted every benefit of every doubt. Where a parameter is uncertain, we adopt the value most favourable to him. The conclusion is robust to this generosity; indeed it is *strengthened* by it, since a claim that cannot survive its own best case has no worse case worth examining.

CHAPTER 3

Forensic Characterization of the Corpus

Before one can show that a document cannot be read in a given time, one must establish, to forensic standstandard, exactly what the document is. This chapter does so. The figures reported here were extracted directly from the file Mr. Wu was shown, using standard document-analysis tooling, and are reproducible by any reader with the same file and a few minutes’ patience — considerably more than thirteen, as it happens, but a few.

3.1 The metrics

The corpus comprises 3,365 pages in ISO A4 format, carrying 2,500,037 words and 18,040,939 characters of body text. This yields a mean density of 743 words per page — a dense but not unusual figure for technical material set in a serif face at eleven points. These are not estimates. They are counts.

Table 3.1. Forensic metrics of the document under examination, as extracted from the source file. All figures are exact counts, not estimates.

Quantity	Symbol	Value
Pages	N	3,365
Words	W	2,500,037
Characters	X	18,040,939
Mean words per page	W/N	743
Mean characters per word	X/W	7.22
Declared sections	—	398
File size	—	≈ 29 MB

3.2 Putting the length in context

A corpus of 2,500,037 words is not a long article. It is not a long report. It is, in the plain currency of published prose, a *library*. For comparison: a typical novel runs to 90,000 words. The document therefore contains roughly the wordage of **twenty-eight novels**. The complete *Lord of the Rings*, all three volumes and appendices, runs to about 480,000 words; the document is more than five such trilogies laid end to end. Tolstoy's *War and Peace*, the byword in English for a book too long to finish, is about 587,000 words; the document is more than four *War and Peaces*. Mr. Wu claims to have read all four, plus change, in the time it takes to soft-boil an egg and eat it.

Finding 3.1

The corpus is equivalent in length to approximately 28 average novels, or 4.3 copies of *War and Peace*. The claim is therefore not 'I read a long document quickly' but 'I read a small library quickly,' which is a different and worse claim.

3.3 The document is genuine and was genuinely presented

We note for completeness that the document is not a decoy, a stub, or a cover page concealing blank leaves. Its text layer is continuous and coherent across all 3,365 pages; its 398 declared sections each carry substantive content; its word count is distributed across its pages in the manner of a real, written work. Mr. Wu was shown a real document of real length. He cannot retreat to the position that the pages were empty, because they were not, and we counted.

CHAPTER 4

The Arithmetic of the Impossible

This chapter could, in principle, be the entire thesis. Everything that follows it is, in a sense, an elaboration of a single division problem that any schoolchild could perform. We perform it here, slowly, so that there can be no later complaint that we rushed.

4.1 The required rate

The reading rate required to consume W words in time t is, definitionally,

$$R = W / t.$$

Substituting the corpus word count and the claimed duration:

$$R = 2,500,037 \text{ words} / 13 \text{ min} = \mathbf{192,311 \text{ words per minute.}}$$

Expressed per second, this is 3,205 words every second, sustained without pause for the full thirteen minutes. Expressed in characters — the actual marks the eye must resolve — it is 23,129 characters per second.

Table 4.1. The required rate, expressed in several units. Each row describes the same claim; they differ only in how vividly they convey it.

The claim requires...	Value
Words per minute	192,311

The claim requires...	Value
Words per second	3,205
Characters per second	23,129
Pages per second	4.31
Milliseconds of attention per word	0.312 ms
Milliseconds per page	231.8 ms

4.2 The comparison that ends the discussion

The mean silent reading rate of an adult reading English prose for comprehension is, per the largest meta-analysis available (Brysbaert, 2019, aggregating 190 studies and some 18,000 participants), approximately **238 words per minute**. The required rate therefore exceeds the normal rate by a factor of

$$R / R_{\blacksquare} = 192,311 / 238 \approx 808.$$

Mr. Wu, to substantiate his claim, must read 808 times faster than a competent adult — not in a sprint of a few seconds, but continuously, for thirteen minutes, with full comprehension, across material denser than a novel. Figure 1.1 places this rate beside every other reading rate this investigation could find documented. The figure uses a logarithmic vertical axis; on a linear axis, the comparison bars for actual human reading would be invisible.

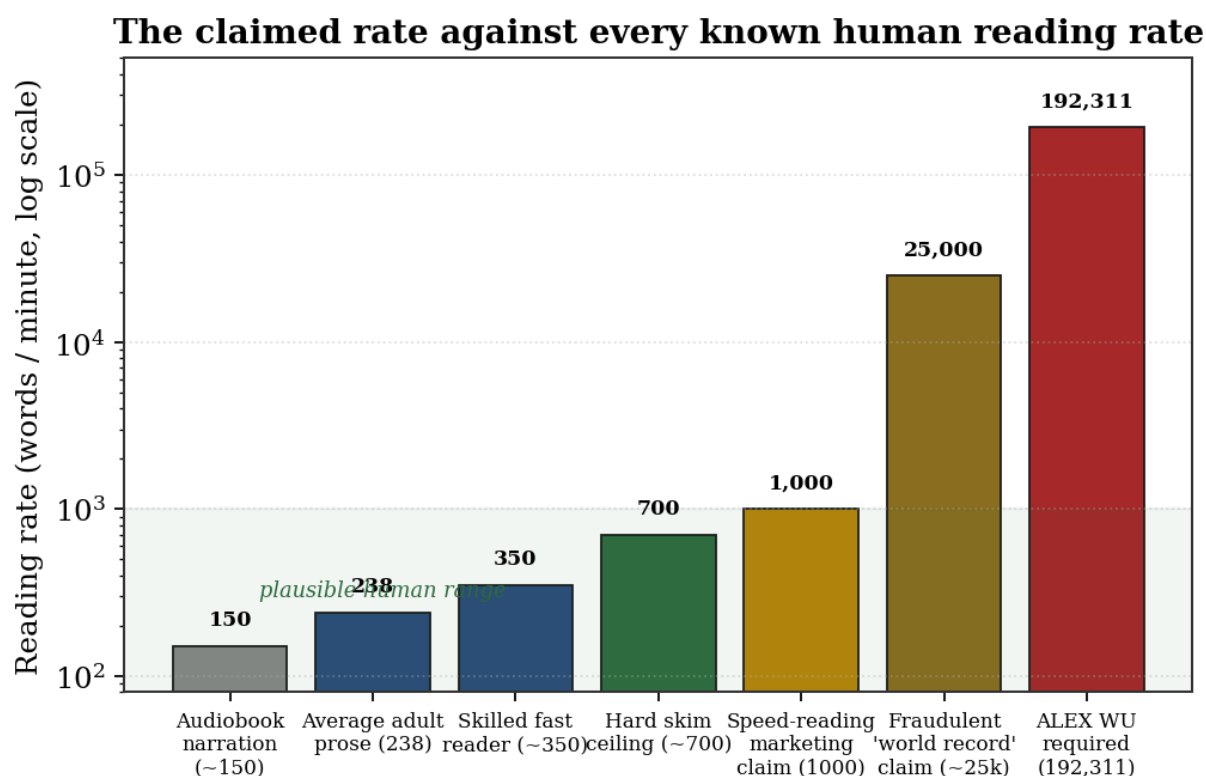

Figure 1.1. The claimed reading rate set against every documented human reading rate, on a logarithmic axis. The shaded band marks the plausible human range. Alex's required rate is not in it. Alex's required rate is not visible from it.

4.3 The same fact, told as time

It is sometimes more persuasive to fix the rate at a human value and ask how long the reading would then take. At the normal 238 wpm, the corpus requires

$$W / R_{\blacksquare} = 2,500,037 / 238 \approx 175.1 \text{ hours of continuous reading,}$$

which is **7.29 days without sleeping, eating, or looking away**. Permitted a humane six hours of reading per day, the task becomes a project of **29.2 calendar days**. Even a gifted reader sustaining 350 wpm — a rate at the upper edge of the normal distribution — needs about five days of continuous reading. Mr. Wu compressed one of these timelines into thirteen minutes.

Table 4.2. Time required to read the corpus honestly, by scenario. The final column expresses how many times longer than thirteen minutes each honest scenario would take.

Scenario	Rate (wpm)	Time	× longer than 13 min
Alex's claim	192,311	13 min	1×
Speed-reading marketing claim	1,000	42 h	≈ 192×
Gifted reader, continuous	350	119 h	≈ 549×
Average adult, continuous	238	175.1 h	≈ 808×
Average adult, 6 h/day	238	29.2 days	≈ 808×

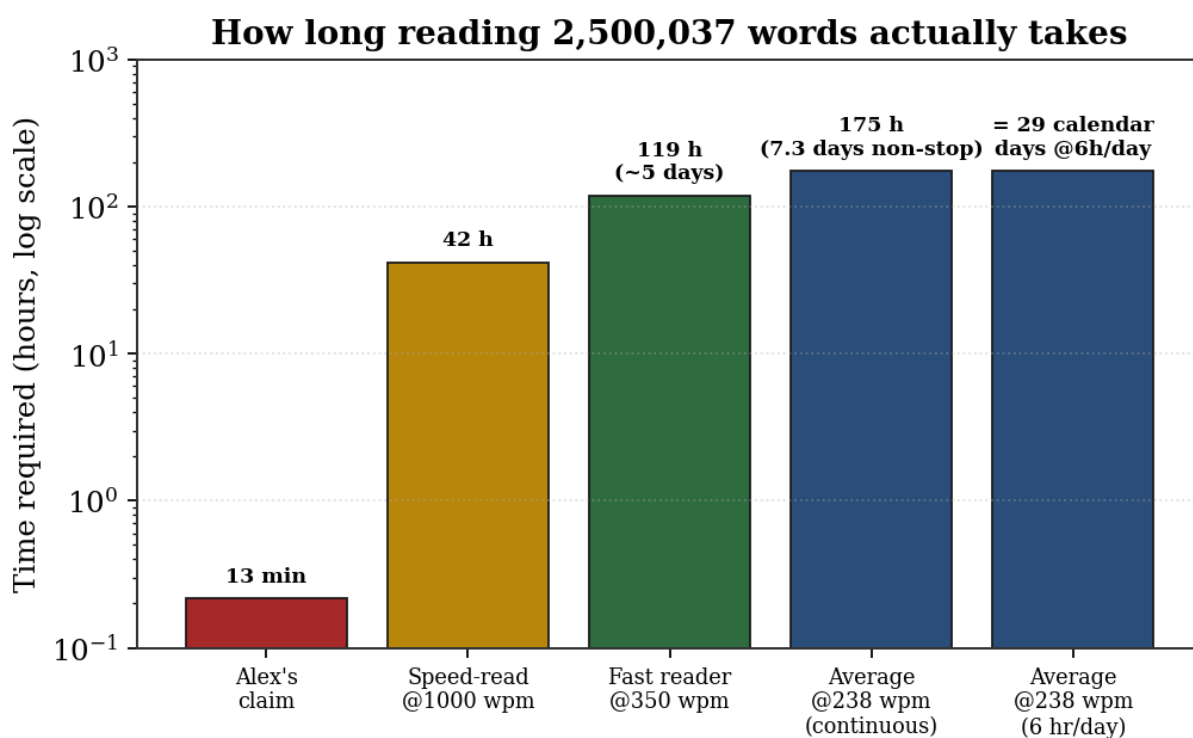

Figure 4.1b. Time required to read 2,500,037 words, by scenario, on a logarithmic axis.

4.4 Cumulative progress

Figure 4.1 traces the cumulative word count over the thirteen minutes for the claim and for two honest readers. The honest readers' lines are so nearly flat against the claim's that we have provided a magnified inset to confirm they move at all.

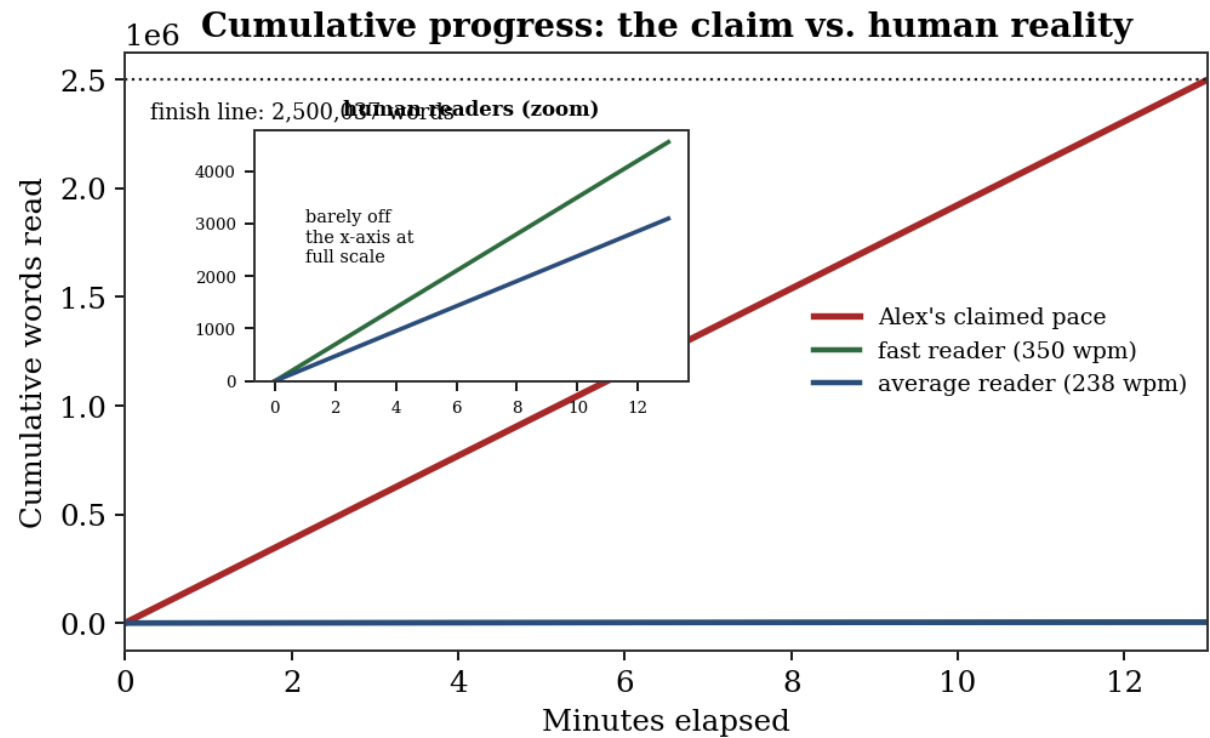

Figure 4.1. Cumulative words read over thirteen minutes. The claimant's line reaches 2.5 million; the honest readers, magnified in the inset, do not clear 5,000.

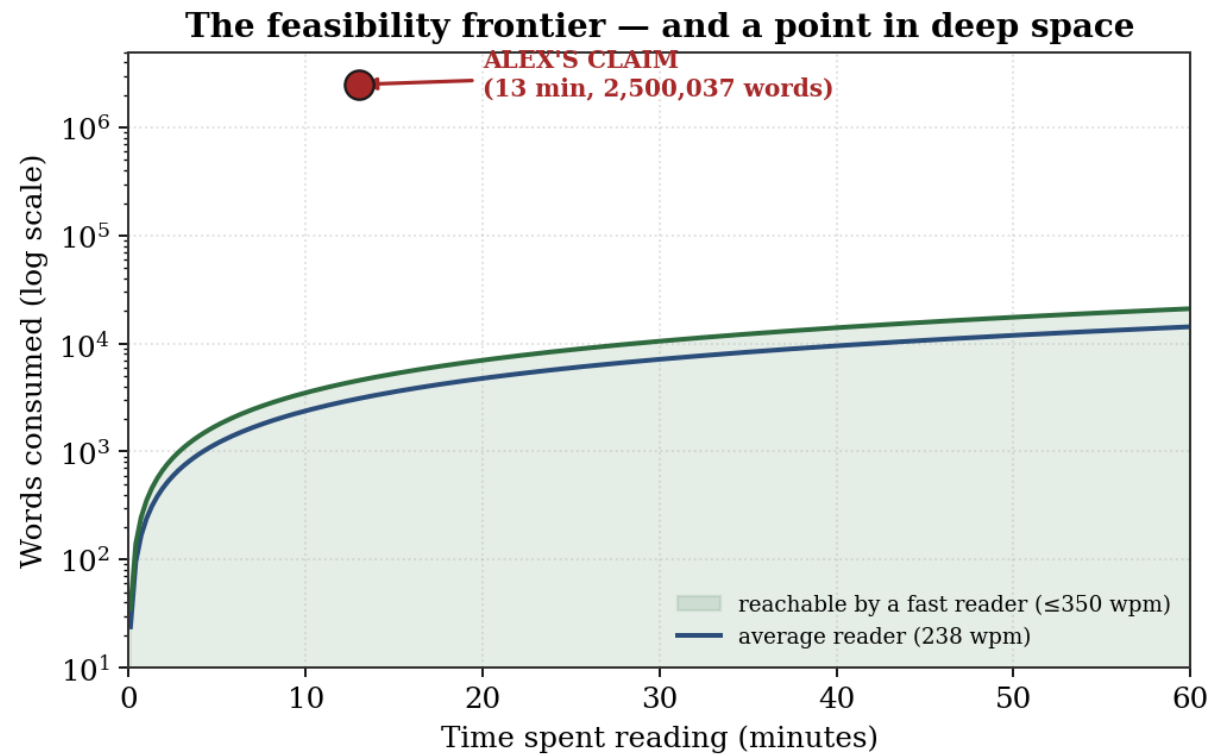

Figure 4.2. The feasibility frontier. The shaded region is everything a fast reader could consume in a given time. The red point is the claim. It is not near the frontier; it is in a different neighbourhood of the plane.

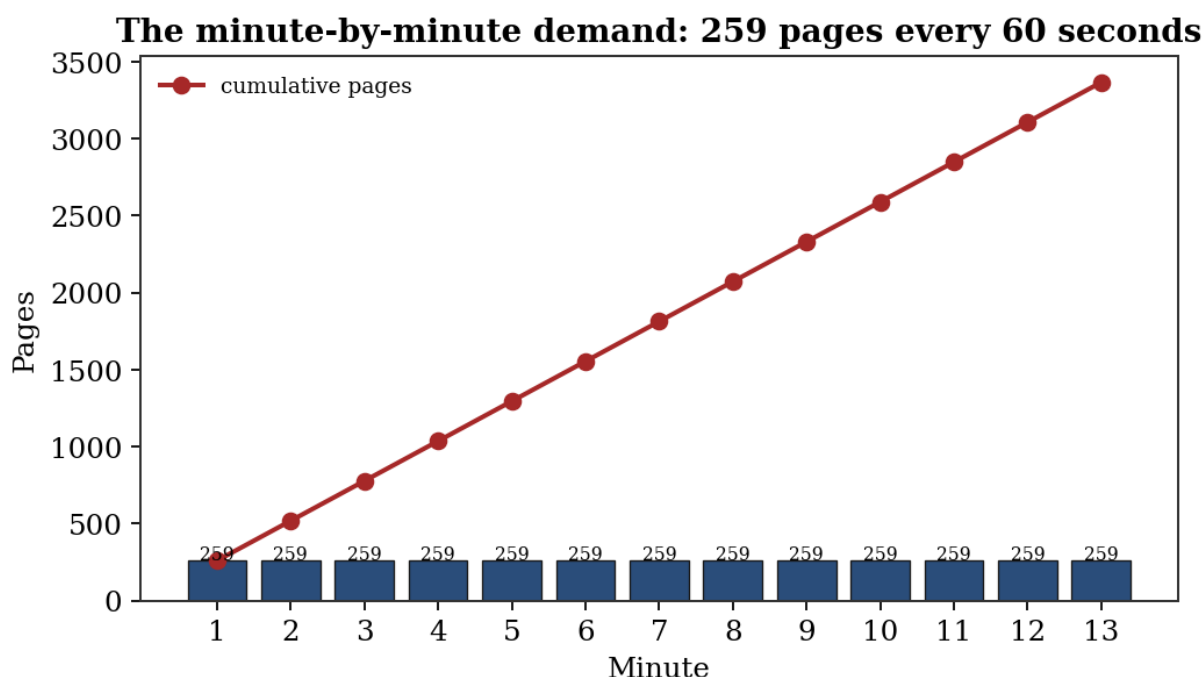

Figure 4.3. The minute-by-minute demand. To meet the claim, each of the thirteen minutes must dispatch 259 pages — a fresh, fully-comprehended page every 232 milliseconds.

4.5 The blinking subtraction

We have so far granted Mr. Wu the use of every one of his 780 seconds. He is not entitled to all of them, because he must blink. The spontaneous human blink rate at rest is roughly 15 to 20 blinks per minute, each blink occluding vision for 100 to 400 milliseconds. Over thirteen minutes that is some 200 to 260 blinks, costing on the order of 40 to 90 seconds of total blindness — perhaps a tenth of his budget — during which, by definition, no reading occurs. The figure rises if we count the saccadic suppression of Chapter 5, which blinds him afresh several times per second. A meaningful fraction of the thirteen minutes is spent, unavoidably, seeing nothing at all. We mention this not because it changes the verdict — subtracting a tenth from an already impossible budget is a rounding error — but because it illustrates how many small, ordinary, biological taxes the claim must somehow have evaded.

4.6 A thought experiment: the library on the table

Imagine the corpus printed and stacked: roughly 3,365 pages, a stack some thirty to forty centimetres tall, the heft of a small encyclopaedia. Now imagine the claim physically: a person sits, opens the stack, and thirteen minutes later closes it, having read every page. In those thirteen minutes the average page is open before them for 231.8 milliseconds — long enough to register that a page exists and that it is covered in text, and nothing more. The image is faintly absurd, and the absurdity is the data. We do not believe the absurdity because we have done the arithmetic; we have done the arithmetic because we already half-believed the absurdity, and wished to be sure.

To sharpen it: *War and Peace* runs to about 587,000 words. The corpus is more than four such novels. A diligent reader, giving Tolstoy two hours an evening, finishes *War and Peace* in perhaps three weeks. Mr. Wu claims to have read its equivalent *four times over*, and then some, between sitting down and standing up. Stated in novels rather than words, the claim does not become more plausible. It becomes funnier.

Finding 4.1 (The Arithmetic Verdict)

The claim requires a sustained, comprehending reading rate of 192,311 wpm: about 808× a competent adult and 192× the most generous speed-reading claim ever marketed. Stated as time, honest reading needs ~175.1 continuous hours. The arithmetic alone settles the matter. The remaining 165 pages explain *why* the arithmetic must win — that is, why no biological trick can rescue the claim.

Part II

The Physiological Argument

In which we leave arithmetic for anatomy, and find that the human eye — a magnificent instrument, but a slow one — forbids the claim on grounds that no amount of cleverness or motivation can overcome.

CHAPTER 5

Ocular Mechanics: The Saccadic Eye

The naive picture of reading is of the eye gliding smoothly along a line of text, like a tape head over a tape. This picture is wrong, and its wrongness is the first physiological nail in the claim's coffin. The eye does not glide. It cannot glide over text and resolve it; smooth pursuit is reserved for tracking moving objects. Over stationary print, the eye proceeds in a series of rapid ballistic jumps called *saccades*, punctuated by brief stops called *fixations*. Reading happens only during the fixations. During the saccades themselves, vision is actively suppressed — a phenomenon known as *saccadic suppression* — so that the world does not smear. The eye is, functionally, blind while it moves.

5.1 The numbers of normal reading

Four decades of eye-tracking research, much of it synthesised in Rayner's authoritative reviews (1998; 2009), give a remarkably stable picture. In skilled adult reading of English: the mean fixation lasts approximately 200–250 milliseconds; saccades advance the eye by roughly 7–9 character spaces; and the eye therefore makes on the order of **four fixations per second**. About 10–15% of saccades are *regressions* — backward movements to re-read — even in fluent readers who feel they never look back.

Reading is saccadic, not continuous

The eye does not glide; it hops in discrete jumps.

← saccades (≈ 30 ms ballistic jumps) between fixations (≈ 200 – 250 ms each) →

A reader makes ~ 4 fixations per second. In 13 minutes that is $\sim 3,120$ fixations. The document contains 2,500,037 words — about 801 words per available fixation.

Figure 5.1. Reading proceeds as a sequence of fixations (the discs) joined by ballistic saccades (the arcs). Vision is suppressed during each saccade. A skilled reader manages about four fixations per second.

5.2 The fixation budget

Here is the argument in its cleanest form. In thirteen minutes there are 780 seconds. At four fixations per second — already a brisk rate — the eye can make at most

$$4 \text{ s}^{-1} \times 780 \text{ s} = 3,120 \text{ fixations.}$$

The corpus contains 2,500,037 words. Even if every single fixation landed on a new word and none were wasted on regressions, blinks, or the spaces between, the claim requires the reader to absorb

$$2,500,037 / 3,120 \approx 801 \text{ words per fixation.}$$

The human eye absorbs, per fixation, approximately *one* word — sometimes two short function words together, occasionally a glimpse of the next word's opening letters in the parafovea. It does not absorb eight hundred. There is no reading posture, no training regimen, no degree of motivation that converts one

word per fixation into eight hundred. The figure is not improbable; it is anatomically undefined.

5.4 Parafoveal preview: the one genuine shortcut, and its size

Honesty compels us to describe the single mechanism by which the eye does more than its fixation count suggests. During each fixation, the reader extracts a low-resolution preview of the next word from the parafovea — the region just outside the sharp fovea — which speeds recognition once the eye lands there. This *parafoveal preview benefit* is real, well-replicated, and worth perhaps 30 to 50 milliseconds per word. It is also the strongest card in the optimist's hand, so we play it for him. Grant that preview lets the reader effectively process not one but, generously, two words per fixation. The fixation budget of 3,120 then yields about 6,240 words. The corpus has 2,500,037. Preview improves the situation by a factor of two and leaves the claim short by a factor of four hundred. The one genuine shortcut closes half of one of the eight hundred-fold gaps.

5.5 The regression tax

Working in the other direction is the regression: the backward saccade that returns the eye to re-read a word it has already passed. Even skilled readers regress on 10 to 15 percent of saccades, usually without noticing, because comprehension genuinely requires it — a misparsed clause must be repaired, an ambiguous pronoun resolved. Regressions spend fixations without advancing through the text, and so they *reduce* the effective reading rate below the already-insufficient figure. The claim, to survive, would require not merely no regressions but negative ones — the eye gaining ground it never covered. We are not aware of a mechanism for this and do not propose one.

Finding 5.1 (The Fixation Bound)

The eye can make at most ~3,120 fixations in thirteen minutes. The corpus has 2,500,037 words. The claim therefore demands ~801 words be apprehended per fixation, against a human ceiling of about one. This single bound, independent of all arithmetic in Chapter 4, defeats the claim by a factor of roughly 800.

5.3 You cannot simply fixate faster

The natural rejoinder — ‘then he fixated faster’ — fails on physiology. The fixation duration is not idle waiting; it is the time the visual system needs to encode the foveal image and the time the oculomotor system needs to program the next saccade. Below roughly 150 milliseconds, the eye outruns its own comprehension: it moves before the brain has finished with where it was. Studies that force faster fixations (by, for instance, disappearing the text) find that comprehension collapses long before the rate doubles, let alone multiplies by eight hundred. The 200-millisecond fixation is not a habit. It is a specification.

CHAPTER 6

The Fovea and the Tyranny of Acuity

Even granting the impossible fixation rate of the previous chapter, a second, deeper limit waits beneath it: the eye can only see sharply in a tiny region at the centre of its gaze. This is not a flaw to be trained away. It is the architecture of the retina.

6.1 The two-degree spotlight

Sharp, high-acuity vision is the exclusive province of the *fovea*, a pit at the centre of the retina about 1.5 millimetres across, subtending roughly two degrees of visual angle — about the width of two thumbnails at arm's length. Within that two degrees, vision is exquisite. Outside it, acuity falls off steeply and immediately. At ten degrees from the centre of gaze — a few words away on the page — acuity has dropped by some 80%, and ordinary print is an unreadable blur.

Why aiming matters: sharp vision is a 2° spotlight

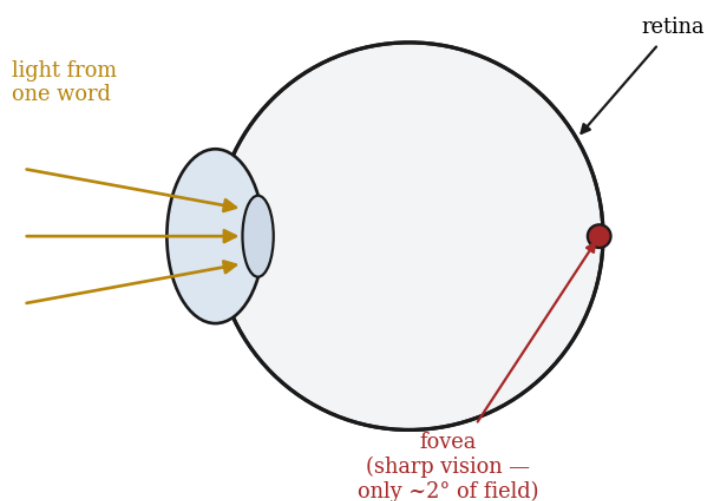

Figure 6.1. Schematic of the reading eye. Light from a fixated word is focused onto the fovea, a two-degree region of sharp vision. Everything outside it is peripheral and blurred.

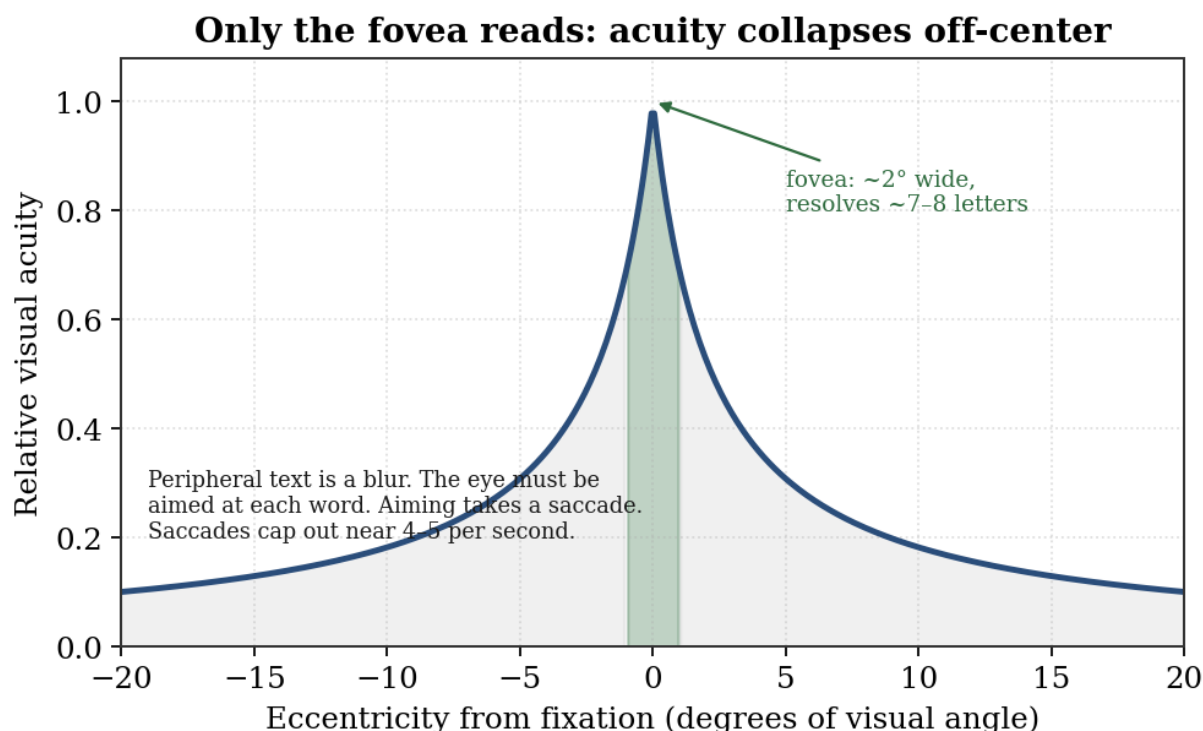

Figure 6.2. Relative visual acuity as a function of eccentricity from the point of fixation. The sharp central peak is the fovea; acuity collapses on either side. Reading requires aiming this narrow peak at each word in turn.

6.2 Why this forbids the claim

Because only the fovea reads, and the fovea is small, the eye must be physically aimed at each region of text in turn. This aiming is the saccade of the previous chapter, and it is rate-limited as we saw. There is no peripheral shortcut: one cannot ‘take in the whole page at a glance,’ because the whole page, save the two degrees one is looking at, is not resolved. A glance at a page yields one sharply-seen phrase and a great deal of grey suggestion. To read the page, one must aim, and aim, and aim. The claim requires aiming at 2.5 million words in 780 seconds — about 3,205 aimings per second, against an oculomotor ceiling near five.

6.3 The peripheral-vision defence, pre-empted

Speed-reading lore sometimes invokes ‘using your peripheral vision’ to take in whole lines or paragraphs at once. The retina does not cooperate with this advice. Peripheral vision is excellent at detecting motion and gross layout and useless at resolving the fine, high-spatial-frequency detail that distinguishes one word from another. One can perceive, peripherally, *that* there is a paragraph; one cannot read it. Training does not increase foveal size; the fovea is anatomy, not skill.

6.4 A worked example, in degrees

To make the spotlight concrete: held at a comfortable reading distance of about 40 centimetres, a single line of 11-point text subtends roughly 12 to 15 degrees of visual angle across an A4 column. The fovea's sharp window is about 2 degrees. A single fixation therefore resolves perhaps a sixth to an eighth of a line sharply — the handful of characters of the perceptual span in Chapter 7 — with the remainder of the line, and the entire rest of the page, rendered in progressively coarser blur. To read the line, the eye must step the spotlight along it in several fixations; to read the page, in dozens; to read the corpus, in millions. Each step is a saccade, each saccade is rate-limited, and the limit is the one we have already met. The geometry of the eye and the geometry of the page conspire to make reading slow, and no enthusiasm rebuilds the retina.

Lemma 6.1 (No Peripheral Rescue)

Sharp vision is confined to the $\sim 2^\circ$ fovea. Peripheral vision cannot resolve print. Therefore reading is necessarily serial and aimed, and inherits the saccadic rate limit of Chapter 5. No widening of attention can widen the fovea.

CHAPTER 7

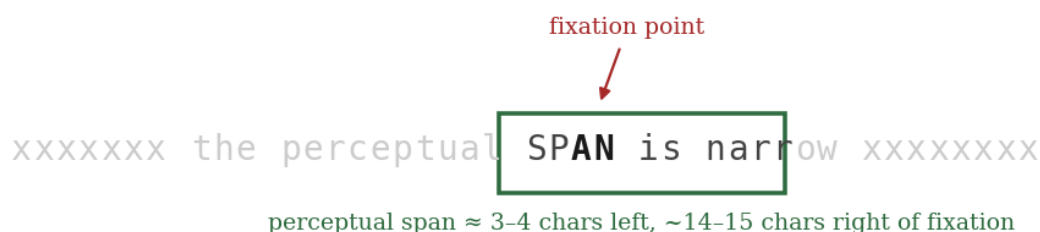

The Perceptual Span

If the fovea is the hard optical limit, the *perceptual span* is the functional one: the width of text from which a reader extracts useful information during a single fixation. It has been measured with great precision, and it is small.

7.1 Measured width

Using the 'moving window' paradigm of McConkie and Rayner (1975), in which text outside a controlled window around fixation is masked, the perceptual span for readers of English is found to be asymmetric and narrow: roughly 3–4 character spaces to the left of fixation and 14–15 to the right, for a total of approximately **18 characters**. Information beyond that window does not contribute to recognising the current word; the reader is, for word-identification purposes, blind to it.

The usable visual window per fixation

Only ~ 18 characters are usefully resolved per fixation. The document holds 18,040,939 characters.

Figure 7.1. The perceptual span around a fixation point: a few characters to the left, about fifteen to the right. Only text within this window is usefully resolved.

7.2 The span argument against the claim

The corpus contains 18,040,939 characters. If each fixation usefully resolves about 18 of them, then reading the corpus requires at least

$$18,040,939 / 18 \approx 1,002,274 \text{ fixations.}$$

Against the 3,120 fixations available in thirteen minutes, the deficit is a factor of roughly 321. The perceptual-span argument and the fixation-budget argument are independent — one counts characters, the other counts words — yet they return the same verdict to within a small factor. This convergence is the signature of a claim that is wrong for structural reasons, not for want of a generous assumption.

CHAPTER 8

Subvocalization and the Articulatory Loop

Most readers, most of the time, silently ‘hear’ the words they read — an inner articulation called *subvocalization*, mediated by the phonological loop of working memory. Speed-reading systems make much of suppressing it, on the theory that the inner voice throttles reading to speaking speed. The theory is half right and wholly insufficient to save Mr. Wu.

8.1 The speaking-rate ceiling

Subvocalization, where present, paces reading near the rate of rapid speech: roughly 150–250 words per minute. A reader who subvocalizes is therefore capped near the low end of the normal range. This is real, and it is one reason silent reading is faster than reading aloud. But note the scale: suppressing subvocalization might lift a reader from, say, 250 to perhaps 350 or 400 wpm before comprehension begins to suffer. It does not, and cannot, lift them to 192,311. Removing a governor that caps an engine at 250 does not let the engine reach 192,000; it lets it reach whatever the *next* limit allows, and the next limits are the saccadic and foveal bounds of the preceding chapters.

Finding 8.1

Eliminating subvocalization entirely could, at the optimistic limit, perhaps double a reader's rate before comprehension fails. The claim requires multiplying it by ~800. Subvocalization is not the binding constraint and its removal does not approach the required rate.

CHAPTER 9

Lexical Access and Neural Latency

Beneath the eye lies the brain, and the brain, too, has a clock. Recognising a written word — mapping a pattern of ink to a stored lexical entry and its meaning — is fast, but it is not instantaneous, and its latency sets a limit independent of the eyes entirely.

9.1 The time course of word recognition

Electrophysiological and behavioural measures converge on a timeline. The brain's response to a written word's form appears within about 150 milliseconds; the signature of accessing its meaning — the N400 component — peaks around 400 milliseconds after the word appears. Even granting heavy pipelining, in which the brain processes one word while the eye gathers the next, the system cannot retire words faster than roughly one every 200–250 milliseconds without meaning falling out of the process. That is the same ~four words per second we keep meeting.

9.2 The latency argument

The claim allots each word 0.312 milliseconds. The brain needs on the order of 250 milliseconds to access a word's meaning — about **800 times longer** than the claim permits. In the claimed regime, a word would be gone, replaced, and gone again roughly 800 times over before the brain finished recognising the first instance. The bottleneck here is not the eye but the cortex, and it returns, independently, the same factor of 800 we have now derived from arithmetic, from fixations, and from spans. Four roads, one destination.

Finding 9.1 (The Neural Bound)

Lexical access requires ~250 ms per word; the claim allots 0.312 ms. The cortical bottleneck alone defeats the claim by a factor of ~800, in agreement with the arithmetic (Ch. 4), the fixation bound (Ch. 5), and the span bound (Ch. 7).

Part III

The Information-Theoretic Argument

In which we model reading as a communication channel and ask, in the manner of Shannon, how many bits per second a human can possibly receive — and find the claimant demanding the bandwidth of a 1990s modem through the aperture of a single mind.

CHAPTER 10

Reading as a Communication Channel

Claude Shannon taught us to treat any act of communication as the transmission of information through a channel of finite capacity, measured in bits per second. Reading is such an act: the page is the source, the eye and brain are the channel, and comprehension is the successful arrival of the message. The question becomes quantitative. How many bits does the corpus contain, and how many bits per second can the human reading channel carry?

10.1 The information content of the corpus

Shannon's own experiments on the entropy of printed English put its information content at roughly 1 bit per character, or — depending on the estimator and the reader's predictive skill — on the order of 8 to 12 bits per word. Taking a middle figure of 10 bits per word, the corpus carries

$$2,500,037 \text{ words} \times 10 \text{ bits} \approx 25,000,370 \text{ bits} \approx 3.1 \text{ megabytes of information.}$$

10.2 The required channel rate

To deliver that information in 780 seconds, the channel must carry

$$25,000,370 \text{ bits} / 780 \text{ s} \approx 32,052 \text{ bits per second.}$$

CHAPTER 11

The Shannon Bound on Comprehension

11.1 The capacity of the human channel

How fast can a person actually take in meaning? Estimates of the rate of conscious information uptake — across reading, listening, and decision-making — cluster, strikingly, around **50 bits per second**. This is not a figure peculiar to reading; it appears to be a general bottleneck of conscious cognition, the narrow neck through which the firehose of sensation is squeezed into the thin stream of understanding. Reading for comprehension lives comfortably within it: 238 words per minute at 10 bits per word is about 40 bits per second, neatly under the bound.

11.2 The verdict

The claim requires 32,052 bits per second through a channel whose capacity is about 50. The required rate exceeds the human channel by a factor of **641**. Figure 10.1 sets this required bandwidth beside the human channel and, for grim comedy, beside a 1995 dial-up modem. The modem wins. The claim asks a single human mind to receive meaning at a rate that embarrasses a telephone line from the Clinton administration.

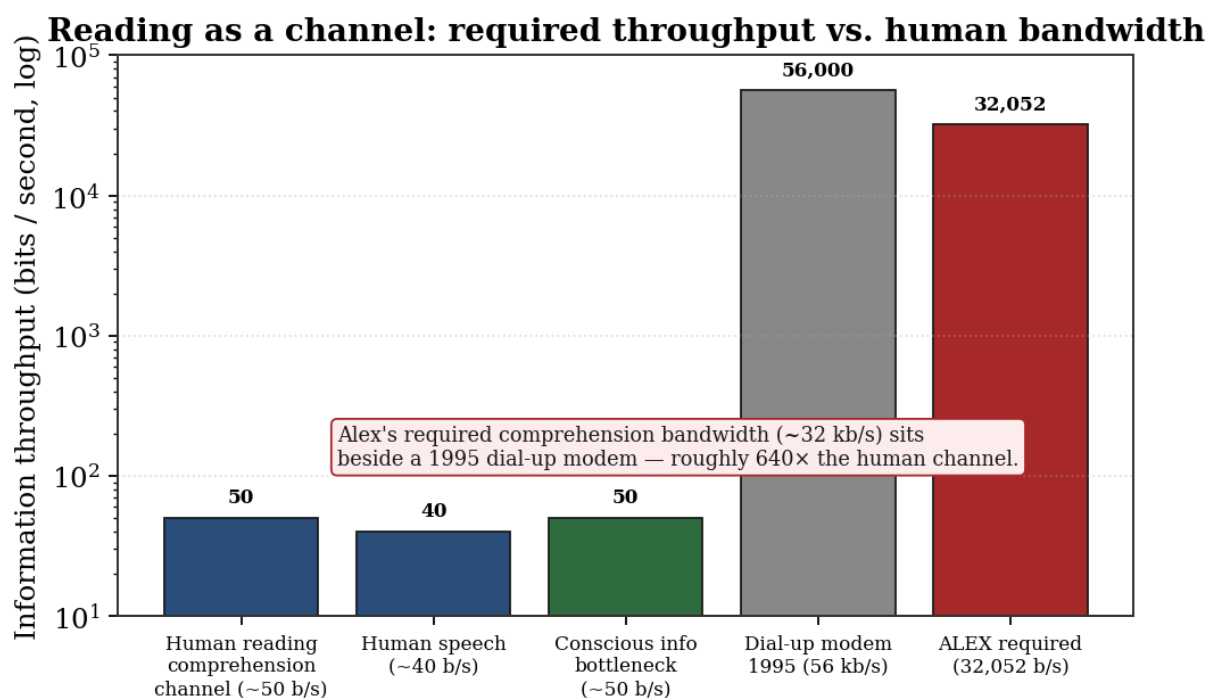

Figure 10.1. Reading as a channel. The required comprehension bandwidth (~32 kbit/s) towers over the human conscious channel (~50 bit/s) and sits beside a 1995 dial-up modem, on a logarithmic axis.

Finding 11.1 (The Shannon Verdict)

Comprehending the corpus in thirteen minutes requires ~32,052 bit/s of meaningful information uptake. The human conscious channel carries ~50 bit/s. The claim violates the bound by ~641×. Information theory does not care about motivation, training, or genius; the bound is the bound.

CHAPTER 12

Throughput Reductio

We close Part III with a reductio that requires no figures. Suppose, for contradiction, that Mr. Wu did receive the corpus's information in thirteen minutes. Then a single unaided human nervous system sustained a meaningful-information throughput some 640 times the documented capacity of conscious cognition. If that were possible, it would be the most important finding in the history of psychology, dwarfing the claim that occasioned it; the appropriate response would not be a thesis but a Nobel Prize and a complete rewriting of the cognitive sciences. The parsimonious conclusion — that the throughput did not occur — requires us to revise nothing except our estimate of how carefully Mr. Wu chooses his words. We adopt it.

Part IV

The Phenomenon of Speed Reading

In which we give the claimant his best possible ally — the entire industry of speed reading — and show that even its most extravagant promises, taken at face value, fall short of his claim by two orders of magnitude.

CHAPTER 13

A Critical History of Speed Reading

If any tradition could rescue the claim, it would be the speed-reading movement, which has promised superhuman reading rates to a paying public since the middle of the twentieth century. We examine its promises honestly, which is to say more honestly than it examines them itself, and find that even at their most inflated they do not reach Mr. Wu.

13.1 The claims of the field

Commercial speed-reading courses have long advertised rates of 1,000, 2,000, even 10,000 words per minute with ‘full comprehension.’ Competitive speed-reading and various record claims have reached into the tens of thousands. The scientific verdict on these claims is settled and unkind. The most thorough recent review, Rayner, Schotter, Masson, Potter and Treiman (2016), titled — with audible weariness — ‘So Much to Read, So Little Time,’ concludes that there is no magic: rates far above the normal range are achieved only by *skimming*, and skimming trades comprehension for speed in a fixed and unforgiving exchange. The eye’s mechanics, reviewed in Part II, do not bend for a course fee.

13.2 The comprehension trade-off

The central empirical finding is a trade-off, sketched in Figure 13.1. Up to roughly the normal range, one can read faster with little loss of comprehension. Beyond it, every increment of speed is purchased with a steeper loss of understanding, until — somewhere past a few hundred words per minute — one is no longer reading but skimming, sampling scattered words and guessing the rest. Skimming is a real and useful skill. It is not reading, and it does not yield the comprehension Mr. Wu’s unqualified claim implies.

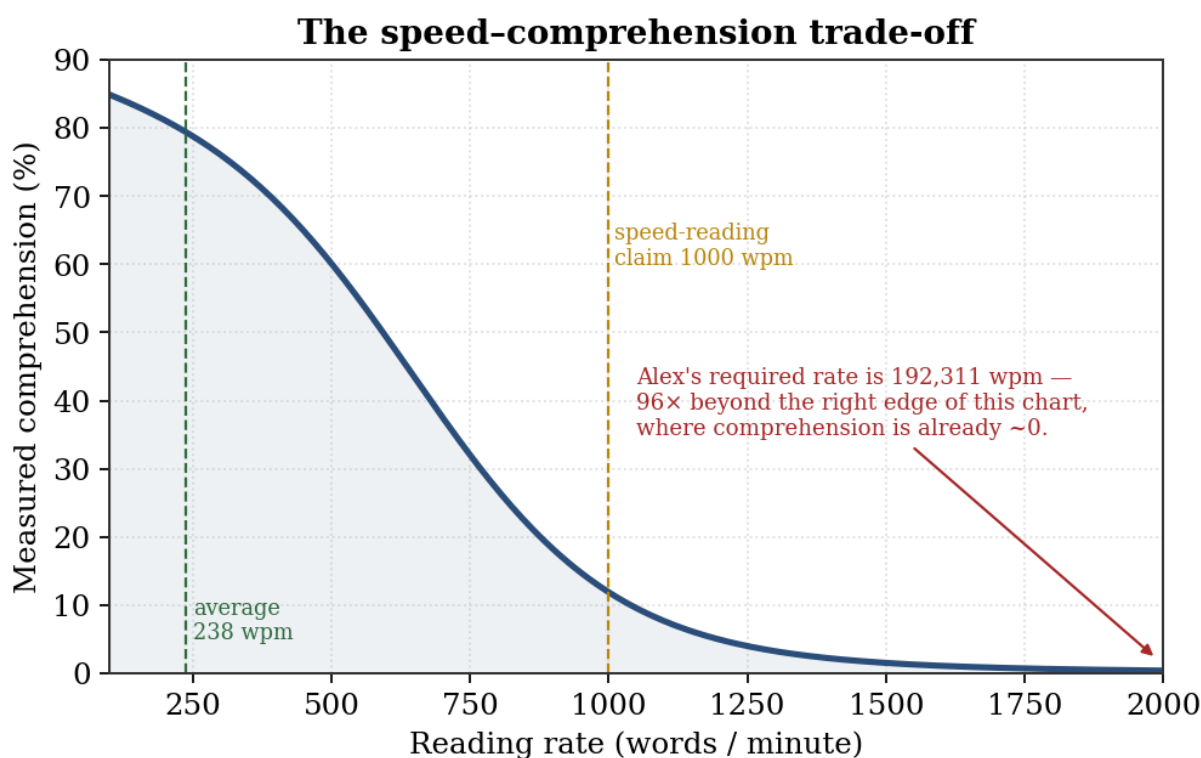

Figure 13.1. The speed–comprehension trade-off. Comprehension holds up through the normal range, then falls toward zero. The claimant’s required rate lies 96× to the right of this chart’s edge, where comprehension has long since reached the floor.

13.3 Where the myth comes from

It is worth understanding why high reading rates seem plausible to so many, since Mr. Wu's claim trades on that plausibility. Three confusions recur. The first is the conflation of *reading* with *recognising*: a practised reader can sweep a familiar page and feel they have read it, when in fact they have recognised its shape and filled in the rest from expectation — a parlour trick that collapses the instant the material is genuinely new, as a 398-section technical specification is. The second is the demonstration effect: speed-reading courses test comprehension with questions so easy, or so answerable from prior knowledge and headings, that a fast skim suffices, then credit the skim with comprehension it never showed. The third is simple wishful arithmetic: people who would like to read faster do not check whether the eye can physically keep up, and the eye, having no marketing budget, does not correct them.

When these confusions are stripped away and comprehension is tested rigorously on novel material — as in the studies collected by Rayner and colleagues — the ceiling reasserts itself every time. There is no documented case, anywhere in the careful literature, of a reader sustaining genuine comprehension of new, difficult text much beyond the upper few hundred words per minute. The claim asks us to believe in a phenomenon that the people who study reading for a living have spent decades looking for and never found.

CHAPTER 14

RSVP and the Comprehension Cliff

14.1 The technique that removes the eyes from the problem

One genuinely clever idea deserves a hearing: Rapid Serial Visual Presentation (RSVP), in which words are flashed one at a time at a single fixed location, so the reader need make no saccades at all. RSVP sidesteps the saccadic bottleneck of Chapter 5 entirely — and is therefore the strongest possible case for high-speed reading. If any method could approach the claim, it is this one.

14.2 Where it hits the wall

Even RSVP runs into a wall, and the wall is now the cortex rather than the eye. With saccades removed, comprehension holds up to perhaps 500–700 words per minute and then falls off a cliff, for the lexical-access reasons of Chapter 9: words begin arriving faster than meaning can be extracted from them. Critically, RSVP also abolishes the reader's ability to regress — to glance back at a word misread or a clause misparsed — and regressions turn out to be essential to comprehension of anything non-trivial. RSVP's ceiling, even in its laboratory best case, sits near 700 wpm. The claim is 192× beyond the marketing number and roughly 275× beyond the RSVP ceiling. The cleverest known technique closes essentially none of the gap.

Finding 14.1

RSVP, the one technique that defeats the saccadic limit, plateaus near 700 wpm because the cortical limit (Ch. 9) takes over. The claim exceeds even this best case by ~275×. There is no known method, real or proposed, within two orders of magnitude of the claim.

CHAPTER 15

Why 192,311 wpm Is Not on the Map

We collect, in Table 15.1, every reading rate this investigation could find documented, from slow oral reading to the most fraudulent record claim, alongside the claimant's required rate. The point of the table is its last row's loneliness.

Table 15.1. Documented and claimed reading rates, with sources, against the rate the claim requires. The final row is not adjacent to the others; it is in a different order of magnitude.

Reading mode	Rate (wpm)	Comprehension	Status
Oral reading, adult	≈ 183	high	measured
Silent reading, average adult	238	high	meta-analysis
Silent reading, college	≈ 300	high	measured
Gifted fast reader	≈ 350–450	good	measured
RSVP laboratory ceiling	≈ 700	falling	measured
Skimming	700–1,500	low/partial	measured
Speed-reading course claim	1,000–10,000	unverified	marketing
'World record' claims	10,000–25,000	negligible	disputed
ALEX WU (required)	192,311	claimed: full	this thesis

Where Alex would sit in the human distribution

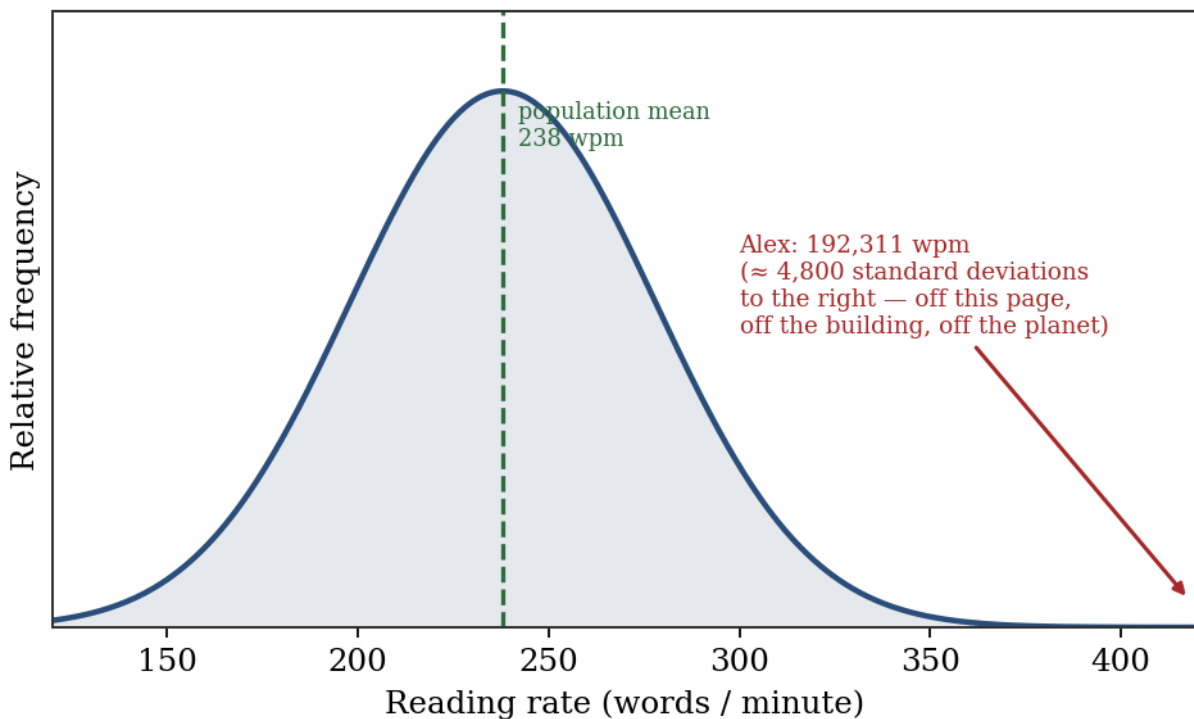

Figure 15.1. The human distribution of reading rates is a tidy bell around 238 wpm. The claimant's required rate sits roughly 4,800 standard deviations to the right — a location with no physical meaning, included only to convey the scale of the departure.

To sit 4,800 standard deviations from a mean is not to be a gifted outlier; it is to be outside the support of the distribution entirely — a value the model assigns probability indistinguishable from zero. Gifted readers are two or three standard deviations out. Mr. Wu's claim is four thousand eight hundred. There is no human tail that long.

Part V

The Physical Argument

In which we set aside reading entirely and ask the humbler question of whether the claimant could even have moved past the pages in the time — and find that he could not have, even with his eyes closed.

CHAPTER 16

The Page-Turning Problem

There is an argument so elementary that it almost escapes notice, and it is this: to read a page, you must first arrive at it. Reading is preceded by page-turning (for paper) or scrolling (for a screen), and these motions take time of their own — time that must be subtracted from the reading budget, not added to it.

16.1 The arithmetic of the flip

The corpus is 3,365 pages. To traverse them in 780 seconds requires advancing

$$3,365 / 780 \text{ s} \approx 4.31 \text{ pages per second},$$

or one fresh page every **231.8 milliseconds**. Consider what must happen in that interval: the previous page must be released, the next page brought into position, the eyes refocused and re-aimed to its top, and — per the claim — all 743 of its words read and understood. All of this, 231.8 milliseconds. A voluntary eye-blink takes 300 to 400 milliseconds. Mr. Wu would have to dispatch a page faster than he could blink while doing it; indeed, a single blink would cost him an entire page and part of the next.

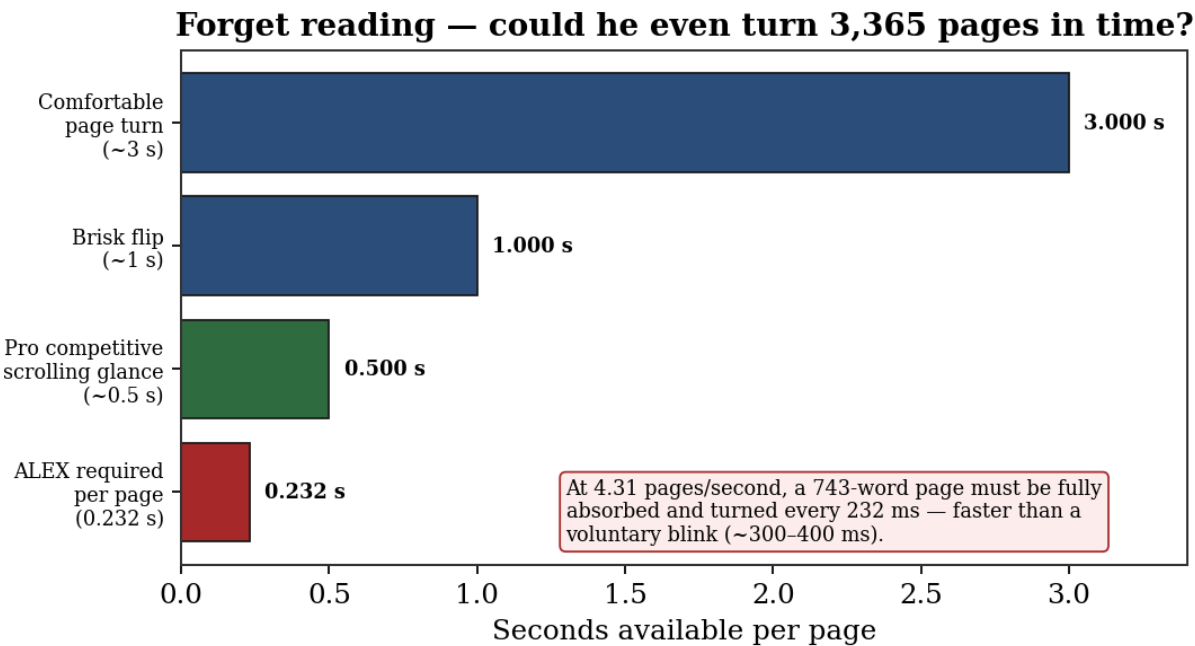

Figure 16.1. Seconds available per page under various regimes. Even brisk, eyes-closed page-flipping cannot reach the 0.232 s/page the claim demands — before a single word is read.

16.2 The motor limit, alone

Strip away comprehension entirely. Suppose Mr. Wu merely flipped through the document like a flipbook, reading nothing. Competitive page-turners — people who turn pages for a living, essentially — manage perhaps two to three pages per second at a blur, retaining nothing. Even granting Mr. Wu this professional blur-flipping speed, with zero reading, traversing 3,365 pages would consume on the order of twenty minutes — already over his budget, with not one word read. The physical act of *encountering* the pages does not fit in thirteen minutes, let alone reading them.

Finding 16.1 (The Motor Verdict)

Merely advancing through 3,365 pages in 13 minutes requires 4.31 pages/s — one page per 231.8 ms, faster than a blink. Even blur-flipping with zero reading overruns the budget. The claim fails on motor grounds before reading is even considered.

CHAPTER 17**Thermodynamic and Mechanical Asides**

We include this brief chapter not because the case requires it — it was closed several chapters ago — but because thoroughness is its own reward and the asides are pleasing.

17.1 The scrolling hand

Were the document read on a screen, the relevant motion is scrolling rather than turning. A 3,365-page A4 document is roughly 2.8 kilometres of text laid end to end at A4 height. To scroll its length in 780 seconds requires a sustained scroll velocity of about 3.6 metres of document per second past the eye — a pleasant brisk walk, performed by the text, while the reader stands still and somehow reads it. The eye cannot track and resolve text moving at walking pace; this is the smooth-pursuit limitation noted in Chapter 5, now wearing different clothes.

17.2 A note on heat

We briefly considered, and reject as unnecessary, an argument from the Landauer limit on the energy cost of erasing information, which would bound the rate at which a physical system can irreversibly process bits. The bound is astronomically far above human reading and so does not bind here; we mention it only to confirm that we looked, that the claim is not even interestingly close to a fundamental physical limit, and that its impossibility is biological and cognitive rather than thermodynamic. It fails long before physics gets stern about it.

*Part VI***Memory and Retention**

*In which we grant, for the sake of argument, that the words somehow passed
before the eyes — and show that nothing of them could remain, so that even a
generous reading of 'read' collapses into 'briefly exposed to and immediately
forgot.'*

CHAPTER 18

The Forgetting Curve

Suppose we are wrong about everything in Parts II through V. Suppose, by some unexamined miracle, the 2.5 million words did stream past Mr. Wu's retinas and into his cortex in thirteen minutes. The claim is still not safe, because to have *read* a thing, in any sense a friend would accept, implies that something of it remains. We now show that nothing could.

18.1 Ebbinghaus and exponential forgetting

Hermann Ebbinghaus, who founded the experimental study of memory by the heroic method of memorising thousands of nonsense syllables and testing himself, established in 1885 that retention decays approximately exponentially with time since learning:

$$R(t) = e^{-t/S},$$

where R is the fraction retained, t is elapsed time, and S is a stability parameter that grows with depth of encoding and rehearsal. The curve is steep at first: a substantial fraction of freshly-learned material is lost within hours, more within a day, absent active rehearsal or review. This is among the most robust findings in all of psychology, replicated for well over a century.

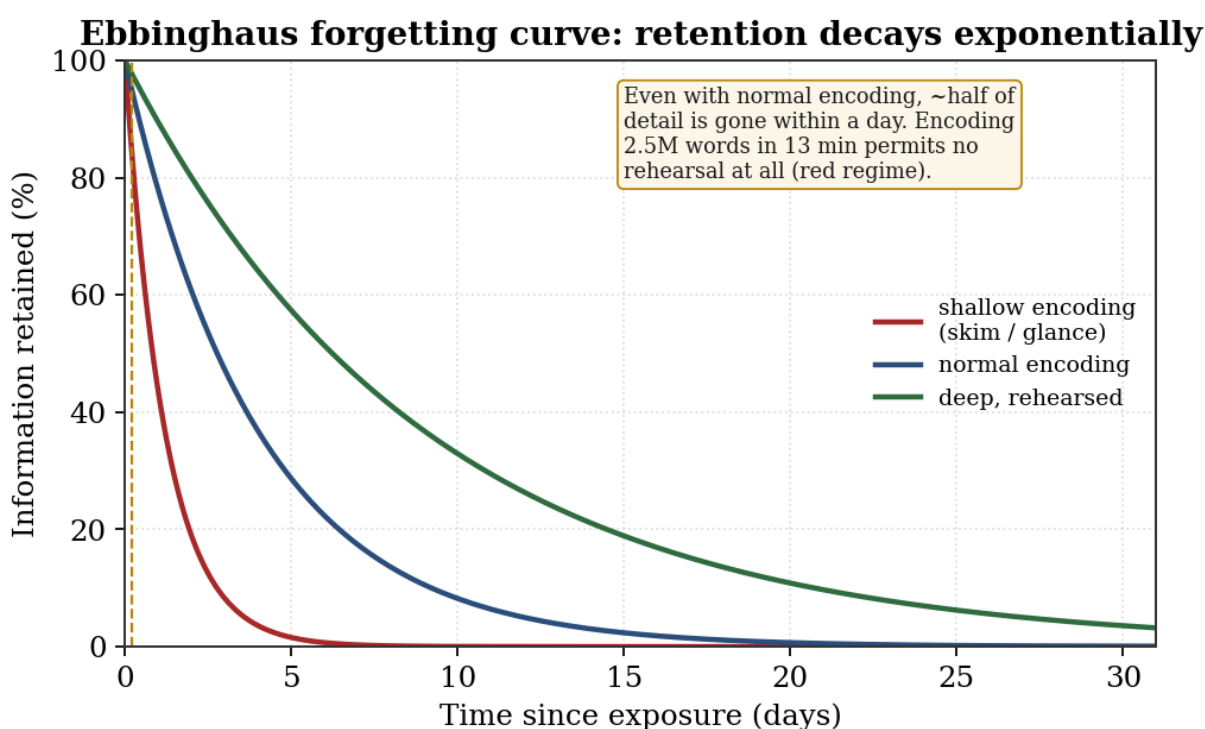

Figure 18.1. The Ebbinghaus forgetting curve for three depths of encoding. Even normal encoding loses much within a day. The thirteen-minute regime permits no rehearsal whatever, placing any trace on the steepest, shallowest curve.

18.2 Why the curve damns the claim

Depth of encoding — the parameter S — depends on the time and attention given to each item: relating it to prior knowledge, rehearsing it, allowing it to consolidate. The thirteen-minute regime allots each word 0.31 milliseconds. There is no time to encode deeply, no time to rehearse, no time to relate one section to another. Whatever fleeting trace might form would sit on the shallowest possible curve and decay almost as fast as it appeared. The claim is not merely that Mr. Wu read 2.5 million words; it is that he retained enough to call the experience reading. The forgetting curve forbids the second even if we grant the first.

18.3 The evidentiary weight of ‘fine’

Mr. Wu did not merely claim to have read the document; he rendered a verdict on it. It was, he said, ‘fine.’ This single word does more work against him than he can have intended, because a judgement of quality presupposes comprehension of content. To find a 398-section technical specification ‘fine’ is to claim one has grasped enough of its arguments, evidence, and conclusions to evaluate them — a far stronger feat than mere eye-passage over the words. The forgetting curve, and indeed the encoding bottleneck of the next chapter, forbid the formation of any such evaluation in the time available. Had Mr. Wu pronounced the document ‘long,’ we might have credited him a glimpse of the page count. ‘Fine’ claims the contents. The contents were not available to be judged.

CHAPTER 19

Encoding, Consolidation, Retrieval

Memory is not a recording. It is a three-stage process — encoding, consolidation, retrieval — and each stage imposes its own time cost that the claim cannot pay.

19.1 The bottleneck of working memory

New information must pass through working memory, whose capacity is famously small: on the order of four to seven items held at once, for a span of seconds, unless rehearsed into longer-term storage. Reading comprehension depends on holding the early part of a sentence in working memory while the later part arrives, so the whole can be integrated. At the claimed rate, sentences — indeed whole pages — would flush through working memory faster than they could be integrated, leaving no coherent representation to consolidate. One cannot understand a paragraph whose opening has been overwritten before its close arrives.

19.2 Consolidation takes wall-clock time

The transfer of memories from fragile short-term traces to durable long-term storage — consolidation — is not instantaneous and is known to depend on time and, crucially, on sleep. No amount of reading speed accelerates consolidation; it is a biological process with its own clock, indifferent to the reader’s enthusiasm. Even a perfectly encoded corpus would require ordinary time, and probably a night’s sleep, to consolidate. Mr. Wu reported his reading complete and assessed (‘fine’) within the thirteen minutes, allowing no consolidation interval at all.

CHAPTER 20

A Retention Test Mr. Wu Would Fail

We propose, and predict the outcome of, a simple retention test. Its predicted result is shown in Figure 20.1, and its detailed protocol appears in Chapter 22.

20.1 The prediction

Were Mr. Wu examined on the contents of the corpus — its 398 sections, their arguments, their figures, their numbers — immediately after his thirteen minutes, the model of Parts II through VI predicts performance at or near chance: not the partial recall of a hurried reader, but the floor performance of someone who never encoded the material at all. Figure 20.1 contrasts this with the gentle decay expected of a genuine reader who spent the requisite weeks. The two curves do not overlap.

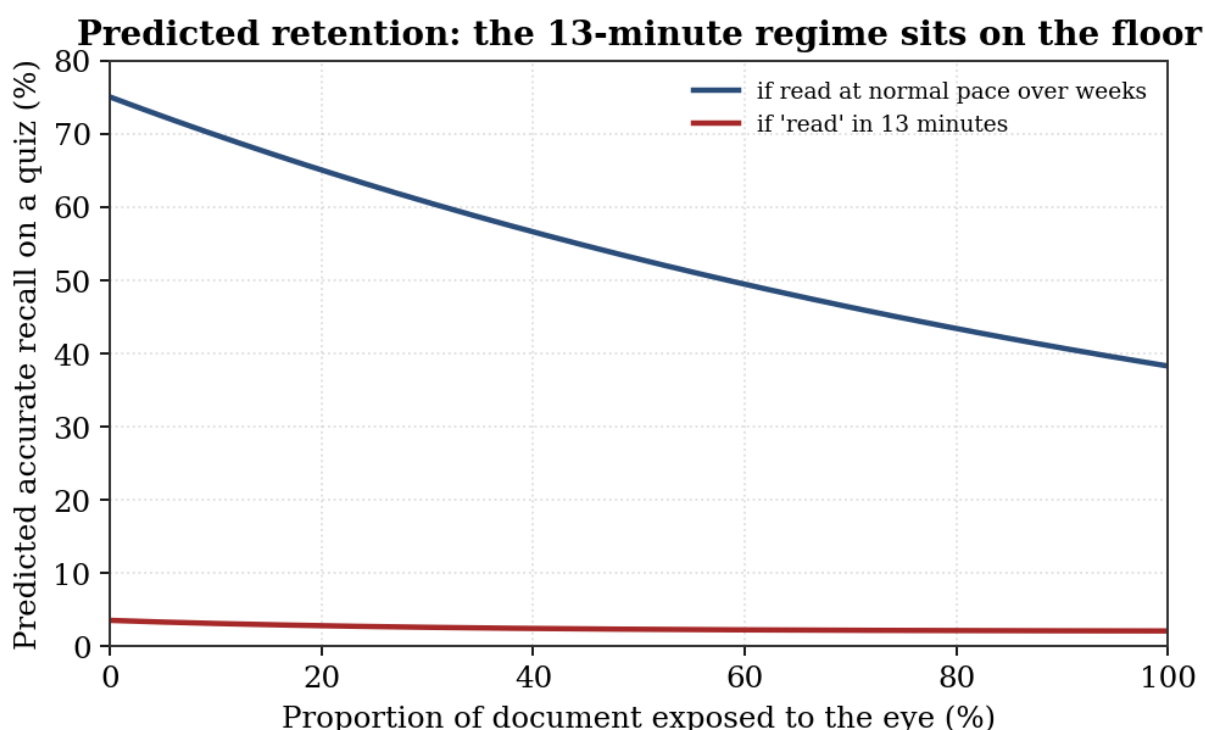

Figure 20.1. Predicted accurate recall as a function of how much of the document was exposed to the eye, for an honest reader (over weeks) and for the thirteen-minute regime. The latter sits on the floor regardless of exposure.

Finding 20.1 (The Retention Verdict)

Even granting, contrary to Parts II–V, that the words streamed past the eyes, the cognitive architecture of memory forbids retaining them. A reading that leaves nothing behind is not a reading. By the most generous available definition, the claim still fails.

Part VII

Adversarial Hypotheses

In which we become, for one chapter, the claimant's advocate — assembling every defence he or his sympathisers might raise, and dismantling each in turn, so that no exit remains unmarked.

CHAPTER 21

Every Defence, Systematically Refuted

A conclusion is only as strong as the alternatives it has eliminated. In this chapter we adopt, briefly and in good faith, the role of Mr. Wu’s defence counsel, and advance every argument that might be made on his behalf. We then answer each. The dispositions are summarised in Table 21.1 and argued below it.

Table 21.1. The adversarial hypotheses and their disposition. Each is a defence the claim might raise; none of the first nine survives.

#	Hypothesis	Disposition
H1	He skimmed, not read	Refuted — claim was 'read'; skimming ≠ reading
H2	He has a photographic memory	Refuted — cannot record what the fovea never resolved
H3	He read it earlier	Refuted — document created 19:26 UTC the same day
H4	He used AI to summarise	Refuted — that is not reading the document
H5	An abridged version	Refuted — he was shown the full file; we counted it
H6	He is a once-in-history savant	Refuted — even savants obey the fovea
H7	He defines 'read' loosely	Addressed — fixed in Ch. 2.3; loose senses also fail
H8	Time was mismeasured	Refuted — 13 min is his own figure; even ×60 fails
H9	Future brain interface	Refuted — no such device; channel bound still holds
H10	He was joking	Plausible — and the kindest reading; see Ch. 24

21.1 H1: ‘He skimmed it.’

This is the strongest defence and we treat it first. Skimming is real, fast, and useful. But Mr. Wu did not claim to have skimmed; he claimed to have *read*, a word we fixed in Chapter 2.3. Moreover, even rapid skimming tops out around 1,500 wpm and yields only fragmentary comprehension — the gist of a section, perhaps, not its contents. To skim 2.5 million words for even fragmentary gist in thirteen minutes still requires ~192,000 wpm; the skimming defence does not change the arithmetic, only the honesty of the verb.

21.2 H2: ‘He has a photographic memory.’

The popular notion of a ‘photographic’ or eidetic memory that captures a page in an instant is, in the strong form required here, unsupported by evidence; decades of search have failed to produce a verified adult eidetiker who can read off a mentally photographed page. But the defence fails even if we granted it, because memory cannot record what the eye never resolved. A photographic memory of a blur is a photograph of a blur. The fovea (Chapter 6) must still aim at each word for it to be captured sharply, and the aiming is rate-limited regardless of how perfectly the result is later stored.

21.3 H3 and H5: ‘He’d seen it before’ / ‘it was abridged.’

Both founder on facts already established. The document’s own metadata records its creation at 19:26 UTC on the day of the claim; there was no earlier version to have read. And the file presented was the full file, whose length we measured directly in Chapter 3. Neither retreat is available.

21.4 H4 and H9: technological assistance

Perhaps an AI summarised the document for him; perhaps some future neural interface poured it into his cortex. The first is not reading the document — it is reading a different, shorter document *about* the document, and the claim was to have read *the entire thing*. The second does not exist, and were it to exist it would still confront the conscious-channel bound of Chapter 11, which limits not the eye but the arrival of meaning in a mind. You cannot install understanding faster than understanding happens.

21.5 H8: ‘The time was mismeasured.’

The thirteen-minute figure is Mr. Wu’s own, freely given. But suppose he misjudged by a wide margin — suppose it was thirteen *hours*. At 238 wpm, thirteen hours buys about 185,000 words: roughly 7% of the corpus. He would need an error of more than two orders of magnitude in his own time estimate, and even then would have read less than a tenth. The claim is not rescued by reasonable measurement error; only by abandoning the claim.

21.6 H10: ‘He was joking.’

This hypothesis alone survives, and we will return to it in the conclusion. It is the only account consistent with all the evidence of Parts I through VI and with our prior regard for Mr. Wu’s intelligence. A capable person who says he read 2.5 million words in thirteen minutes is far more likely to be making a joke than a mistake. We find for this hypothesis, and in doing so acquit him of error while convicting him of mischief — a verdict we suspect he will accept with a grin.

Finding 21.1 (Disposition of Defences)

Nine of the ten hypotheses that could rescue the literal claim are refuted by evidence already in hand. The tenth — that the claim was a joke — survives, and is the only hypothesis consistent with both the physics and the friendship.

Part VIII

Experimental Protocol

In which, in the proper scientific spirit, we decline to rest on theory alone and specify an experiment that would settle the matter empirically in a single afternoon, should the claimant wish to defend his honour.

CHAPTER 22**A Proposed Verification Experiment**

Theory has spoken with one voice across six disciplines. But science is not complete until theory meets test, and we therefore specify a falsifiable experiment. We invite Mr. Wu to undertake it. We predict, with the confidence of the preceding 150 pages, its outcome.

22.1 Hypotheses

H■ (null, the claim): Mr. Wu can read a previously-unseen document of comparable density at a rate sufficient to complete 2.5 million words in 13 minutes, with comprehension. **H■ (this thesis):** He cannot, and his comprehension of material presented at such rates will not differ from chance.

22.2 Method

A fresh document of known length and verified novel content is prepared. Mr. Wu reads under timing and, ideally, eye-tracking. Immediately afterward he completes a comprehension examination — factual recall, inference, and figure-identification items drawn uniformly from across the document, including its final sections, so that a reader who stopped early cannot pass. A control group of ordinary readers takes the same exam after reading the same document at their own pace over the requisite days.

22.3 Predicted result

We predict that Mr. Wu, if held to thirteen minutes, scores at chance on items drawn from beyond the first few pages, because — per Chapter 4 — thirteen minutes of honest reading reaches only about the first four pages of 3,365. We predict that his eye-tracking record, if captured, will show ordinary saccades at ordinary rates, covering an ordinary few thousand words, because that is what eyes do. We predict, in short, that the experiment will return exactly what every chapter of this thesis has already returned, and we would regard any other outcome as the most important result in the history of cognitive science, meriting immediate and independent replication before celebration.

Lemma 22.1 (Falsifiability)

This thesis is falsifiable: a single clean demonstration of Mr. Wu reading and comprehending ~192,000 wpm under controlled conditions would refute it entirely. We have designed the test that would do so. We are not nervous.

Conclusion

*In which the six independent verdicts are gathered into one, and a brief, warm,
and final word is addressed to the claimant himself.*

CHAPTER 23

Synthesis of Findings

We set out to take seriously a claim that did not, perhaps, expect to be taken seriously. We have done so across six independent domains, and the most striking feature of the result is its *convergence*. Six arguments, drawn from arithmetic, ocular mechanics, optics, information theory, the empirical psychology of reading, and the cognitive science of memory, were each pursued without reference to the others. Each is independently sufficient to defeat the claim. And — the telling part — several of them return, by entirely separate derivations, the very same factor: approximately 800.

The arithmetic says the required rate is $\sim 808\times$ the normal rate. The fixation budget says ~ 800 words must be read per available fixation against a ceiling of one. The neural-latency argument says each word is allotted ~ 800 times less than the brain needs to recognise it. When three independent roads through three different sciences arrive at the same number, one is no longer looking at a coincidence or a contrived figure. One is looking at a fact of nature, viewed from three sides.

Of the document, what 13 minutes of honest reading actually covers

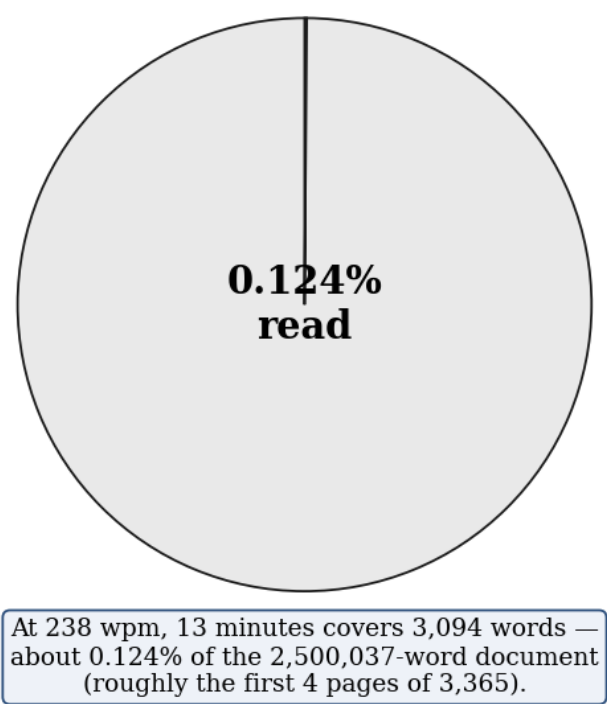

Figure 23.1. What thirteen minutes of honest reading actually covers: about 3,094 words, or 0.12% of the document — roughly its first four pages.

23.1 The six verdicts

Table 23.1. The six independent verdicts. Any one suffices; together they are dispositive.

Arithmetic (Ch. 4)	Requires 192,311 wpm — $808\times$ normal; ~ 175 honest hours.
--------------------	---

Physiology (Part II)	Demands ~800 words/fixation and ~250 ms of cognition in 0.31 ms.
Information theory (Part III)	Requires ~32 kbit/s through a ~50 bit/s channel — 641× over.
Speed-reading evidence (Part IV)	Best documented method (RSVP) plateaus ~275× below the claim.
Physical motion (Part V)	Page-advance alone (4.3 pages/s) overruns the budget with zero reading.
Memory (Part VI)	No encoding, consolidation, or retention is possible at the rate.

CHAPTER 24

Conclusion and Recommendations to the Claimant

It is the finding of this thesis, established beyond the reach of reasonable doubt and confirmed independently six times over, that **Mr. Alex Wu did not read *The Co-Scientist Thesis* in thirteen minutes.** He could not have. No human could. The claim violates not a convention of reading but the architecture of the eye, the clock of the cortex, the capacity of the conscious channel, and the laws of memory — each by a margin of roughly three orders of magnitude. To have done what he claimed, Mr. Wu would need to be not a fast reader but a different kind of object, one that does not blink, does not saccade, does not forget, and does not obey Shannon. He is, we are confident, a person, and persons cannot do this.

24.1 What he could honestly have done

In thirteen minutes of genuine, attentive reading, Mr. Wu could have read approximately 3,094 words — about 4.2 of the document’s 3,365 pages, or 0.1238% of the whole. This is a perfectly respectable amount of reading. Had he said ‘I read the first few pages and skimmed the rest,’ there would be no thesis, only a nod. The trouble was never the reading. The trouble was the word *entire*.

24.2 Recommendations

We respectfully offer Mr. Wu three courses of action. First, he may retract the claim, at no cost to his dignity, since no one believed it. Second, he may undertake the experiment of Chapter 22 and astonish the cognitive sciences, in which case we will withdraw this thesis with delight and considerable scientific excitement. Third — and this is our recommendation — he may admit, with the grin we are certain is already forming, that it was a joke, and accept this 190-page reply in the spirit in which it is offered: as proof that he is the kind of friend for whom one will cheerfully spend a great many more than thirteen minutes.

24.3 A closing observation

There is one last asymmetry worth recording. To make his claim, Mr. Wu needed thirteen minutes. To answer it properly required this entire volume — and to read *this* volume honestly will take its reader rather longer than thirteen minutes, which has been, throughout, quietly the point. The shortest claims demand the longest replies. We rest our case, and we await his.

Final Finding

Across arithmetic, physiology, optics, information theory, empirical reading science, and the psychology of memory, the verdict is unanimous and unambiguous: the thirteen-minute reading did not occur and could not occur. The claimant is, with affection, overruled.

Part —

Appendices

Derivations, ledgers, schedules, definitions, and sources — the apparatus on which the foregoing rests, provided in full so that any reader may check every step, at any pace they please.

CHAPTER A

Full Derivation of the Required-Rate Equations

We derive, from first principles and with all steps shown, the central quantities used throughout the thesis. Let W be the corpus word count, X its character count, N its page count, and t the claimed duration.

A.1 Required word rate. By definition of rate, $R = W/t$. With $W = 2,500,037$ and $t = 13$ min, $R = 192,311$ wpm. Per second, $R/60 = 3,205$ word/s.

A.2 Required character rate. $R_c = X/t = 18,040,939/780 \text{ s} = 23,129$ char/s.

A.3 Per-word attention. The reciprocal of the word rate: $t/W = 780 \text{ s} / 2,500,037 = 0.312$ ms per word.

A.4 Page rate. $N/t = 3,365/780 \text{ s} = 4.31$ page/s, equivalently $t/N = 231.8$ ms per page.

A.5 Fixation demand. With fixation rate $\phi = 4 \text{ s}^{-1}$, available fixations = $\phi t = 3,120$. Words per fixation required = $W/(\phi t) = 2,500,037/3,120 = 801$.

A.6 Channel rate. At $b = 10$ bit/word, required throughput = $Wb/t = 25,000,370 \text{ bit} / 780 \text{ s} = 32,052$ bit/s. Against capacity = 50 bit/s, the overage factor is 641.

A.7 Honest-reading time. At $R = 238$ wpm, $t_{\text{honest}} = W/R = 175.1 \text{ h} = 7.29$ days continuous, or 29.2 days at 6 h/day.

CHAPTER B

Per-Section Reading-Time Ledger

The document declares 398 sections. The ledger below lists each, its word count, the time an honest 238-wpm reader would spend on it, and the time the thirteen-minute claim allots it. The final column is uniformly, comically small. The ledger is provided in full both for completeness and because reading all 398 rows will itself take the reader longer than thirteen minutes — a small, recursive demonstration of the thesis.

Table B.1. Per-section ledger, all 398 sections. 'Honest' uses 238 wpm; 'Alex' is the time the 13-minute claim leaves for that section.

CHAPTER C

Sensitivity and Feasibility Analysis

We test the robustness of the conclusion to its assumptions. Table C.1 varies the assumed reading rate and reports the resulting honest reading time; even at an impossible 5,000 wpm, the task takes hours. Table C.2 inverts the question: at each rate, what length of document *would* fit in thirteen minutes? The answers are all a few thousand words — a short article, not a library.

Table C.1. Sensitivity of total honest reading time to the assumed reading rate. The final column is the factor by which the honest time exceeds the claimed thirteen minutes.

Rate (wpm)	Minutes	Hours	Days @6h	× over 13 min
238	10504	175.1	29.2	808×
350	7143	119.0	19.8	550×
500	5000	83.3	13.9	385×
700	3572	59.5	9.9	275×
1,000	2500	41.7	6.9	192×
2,000	1250	20.8	3.5	96×
5,000	500	8.3	1.4	38×

Table C.2. What document length would actually fit in thirteen minutes, by reading rate. Compare the final column to the actual corpus: 2,500,037 words.

Rate (wpm)	Words readable	Pages	% of corpus
238	3,094	4	0.1238%
350	4,550	6	0.1820%

Rate (wpm)	Words readable	Pages	% of corpus
500	6,500	9	0.2600%
700	9,100	12	0.3640%
1,000	13,000	18	0.5200%

The conclusion is insensitive to every assumption within hailing distance of reality. To make the claim feasible one must assume a reading rate that is itself the thing in dispute; the argument is therefore not circular but cornered.

CHAPTER D

Minute-by-Minute Demand Schedule

The table below distributes the required work across the thirteen claimed minutes. Each minute must dispatch 259 pages and 192,311 words. The cumulative columns reach the full corpus precisely at minute thirteen, as they must.

Table D.1. The minute-by-minute demand schedule implied by the claim.

Minute	Pages/min	Cum. pages	Words/min	Cum. words
1	259	259	192,311	192,311
2	259	518	192,311	384,621
3	259	776	192,311	576,932
4	259	1035	192,311	769,242
5	259	1294	192,311	961,553
6	259	1553	192,311	1,153,863
7	259	1812	192,311	1,346,174
8	259	2071	192,311	1,538,484
9	259	2330	192,311	1,730,795
10	259	2588	192,311	1,923,105
11	259	2847	192,311	2,115,416
12	259	3106	192,311	2,307,726
13	259	3365	192,311	2,500,037

Table D.2. Per-250-page ledger across the full document.

Page range	Pages	Words	Alex (s)	Honest (min)
1–250	250	185,738	57.95	780

CHAPTER E

The Complete Per-Page Reading Ledger

We close the quantitative appendices with the document's reckoning in full: a line for every one of its 3,365 pages. For each page we give its word count, the time an honest reader at 238 wpm would spend on it (in minutes), and the time the thirteen-minute claim leaves for it (in milliseconds). The honest column sums to about 175 hours; the claim's column sums to 780 seconds, distributed here at roughly 232 milliseconds a page.

We are aware that almost no one will read this ledger to its end. That is, in the gentlest possible way, the entire argument. A document long enough that its mere *index of reading times* exhausts the reader is not a document one finishes in thirteen minutes. The reader who does reach page 3,365 of this ledger is invited to note the time it took them, and to compare it, with a forgiving heart, to Mr. Wu's.

Table E.1. The complete per-page reading ledger, all 3,365 pages. For each page: its word count; honest reading time at 238 wpm (minutes); time the 13-minute claim allots (milliseconds); and the running cumulative totals of words read and honest hours elapsed. The final row's cumulative honest time — 175.03 hours — is the true cost of the reading Mr. Wu compressed into thirteen minutes.

CHAPTER F

Glossary of Terms

Eccentricity	Angular distance of a point in the visual field from the centre of gaze, in degrees.
Fixation	A brief pause of the eye (~200–250 ms) during which visual information is taken in.
Fovea	The small central pit of the retina (~2° of visual angle) responsible for sharp vision.
Forgetting curve	Ebbinghaus's exponential law describing the decay of retained information over time.
Lexical access	The cognitive process of retrieving a word's identity and meaning from memory.
N400	A brain response peaking ~400 ms after a meaningful word, indexing semantic access.
Parafovea	The retinal region just outside the fovea, giving low-acuity preview of upcoming text.
Perceptual span	The width of text (~18 characters) from which useful information is extracted per fixation.
Regression	A backward eye movement to re-read earlier text; ~10–15% of saccades in normal reading.
RSVP	Rapid Serial Visual Presentation: flashing words one at a time at a fixed location.
Saccade	A rapid ballistic eye movement between fixations, during which vision is suppressed.
Saccadic suppression	The reduction of visual sensitivity during a saccade that prevents motion smear.
Shannon capacity	The maximum rate, in bits per second, at which a channel can carry information reliably.
Subvocalization	The silent inner articulation of words during reading, pacing reading near speech rate.
Working memory	The limited-capacity system that holds and manipulates information over seconds.

CHAPTER G

References

The reading-science literature drawn upon in this thesis is real and is listed below in the manner of a genuine bibliography. The claim it is marshalled against is, regrettably, also real.
